

West Nile Virus

West Nile Virus (WNV) is a mosquito-borne virus that was first detected in the United States in 1999 in the New York City area. The virus has since been identified in all 48 continental states and the District of Columbia. West Nile Virus may cause a wide range of clinical illness from mild, “flu-like” symptoms, to encephalitis (inflammation of the brain) that may be fatal to both humans and horses. While horses are susceptible to WNV, many horses infected with the disease will not develop any illness and will recover uneventfully. Currently, there is no specific treatment for WNV.

Virus Life Cycle

Mosquitoes acquire WNV from infected birds and pass it on to other birds, animals, and people. Mosquitoes have not demonstrated the ability to feed on an infected horse and ingest enough of the virus to transmit it to other animals. Migratory birds are an important reservoir for WNV and have served as the major vector for spread of the virus into new areas.

Clinical Signs

Consult your veterinarian if your horse exhibits any of the following signs:

- Incoordination, especially in rear limbs causing stumbling and falling
- Drooping lips and lip smacking
- Generalized weakness
- Muscle twitching
- Head drooping, lethargy, and unresponsiveness
- Grinding teeth
- Hypersensitivity to touch or sound
- Fever
- Recumbency (inability to rise)
- Seizures and coma

California Surveillance Efforts

The California Department of Food and Agriculture (CDFA) works with federal, state and local health and agricultural agencies to minimize the impact of WNV on the equine industry. West Nile Virus surveillance includes sampling dead birds, sentinel chickens, mosquito pools, horses, and humans.

CDFA confirms possible equine WNV cases, maintains horse surveillance data, and educates horse owners on control and prevention. The information collected is used by collaborating agencies to focus disease control efforts.

California Outbreak

West Nile Virus was first diagnosed in October 2003 in a 20-year-old unvaccinated Missouri Fox Trotter. In 2004, California became the disease epicenter with 540 confirmed clinical cases of WNV. All confirmed cases were laboratory positive and demonstrated compatible signs. Cases affected 32 of the 58 CA counties. A high percentage of these horses died or were euthanized. Only 22 of the 540 cases were fully vaccinated.

Vaccination

There are currently two approved WNV vaccine products available for horses. An initial series of at least two vaccinations, followed by periodic ‘booster’ injections is required with each.

Horse owners are urged to consult their veterinary practitioner to ensure the vaccination status of all their horses is current.

Mosquito Control

You can decrease the chances of your horse being exposed to WNV by minimizing their exposure to mosquitoes, especially during the peak mosquito feeding period which is dusk to dawn. Applying mosquito repellent also effectively reduces the number of mosquito bites.

Additionally, mosquito breeding sites should be eliminated. Methods for eliminating mosquito-breeding sites include:

- Drain unnecessary standing water: wheelbarrows, tires, etc.
- Clean water containers: bird baths, plant saucers, etc., at least weekly
- Schedule pasture irrigation to minimize standing water
- Keep swimming pools optimally chlorinated and drain water from covers
- Stock water tanks with fish that consume mosquito larvae (local mosquito control may provide assistance), or use mosquito “dunk” available at hardware stores
